1 Secrets in the United Nations

The United Nations (for the purposes of this question) consists of n countries, each having k representatives. A vault in the United Nations can be opened with a secret combination $s \in \mathbb{Z}$. The vault should only be opened in one of two situations. First, it can be opened if all n countries in the UN help. Second, it can be opened if at least m countries get together with the Secretary General of the UN.

(a) Propose a scheme that gives private information to the Secretary General and n countries so that s can only be recovered under either one of the two specified conditions.

(b) The General Assembly of the UN decides to add an extra level of security: in order for a country to help, all of the country's k representatives must agree. Propose a scheme that adds this new feature. The scheme should give private information to the Secretary General and to each representative of each country.

2 Berlekamp-Welch Warm Up

(a) When does $r_i = P(i)$? When does r_i not equal $P(i)$?

(b) If you want to send a length-n message, what should the degree of $P(x)$ be? Why?

(c) If there are at most k erasure errors, how many packets should you send? If there are at most k general errors, how many packets should you send? (We will see the reason for this later.) Now we will only consider general errors.

(d) What do the roots of the error polynomial $E(x)$ tell you? Does the receiver know the roots of $E(x)$? If there are at most k errors, what is the maximum degree of $E(x)$? Using the information about the degree of $P(x)$ and $E(x)$, what is the degree of $Q(x) = P(x)E(x)$?

(e) Why is the equation $Q(i) = P(i)E(i) = r_i E(i)$ always true? (Consider what happens when $P(i) = r_i$, and what happens when $P(i)$ does not equal r_i.)

(f) In the polynomials $Q(x)$ and $E(x)$, how many total unknown coefficients are there? (These are the variables you must solve for. Think about the degree of the polynomials.) When you receive packets, how many equations do you have? Do you have enough equations to solve for all of the unknowns? (Think about the answer to the earlier question - does it make sense now why we send as many packets as we do?)

(g) If you have $Q(x)$ and $E(x)$, how does one recover $P(x)$? If you know $P(x)$, how can you recover the original message?

3 Berlekamp-Welch for General Errors

Suppose that Hector wants to send you a length $n = 3$ message, m_0, m_1, m_2, with the possibility for $k = 1$ error. For all parts of this problem, we will work mod 11, so we can encode 11 letters as shown below:

A	B	C	D	E	F	G	H	I	J	K
0	1	2	3	4	5	6	7	8	9	10

Hector encodes the message by finding the degree ≤ 2 polynomial $P(x)$ that passes through $(0, m_0)$, $(1, m_1)$, and $(2, m_2)$, and then sends you the five packets $P(0), P(1), P(2), P(3), P(4)$ over a noisy channel. The message you receive is

$$\text{DHACK} \Rightarrow 3, 7, 0, 2, 10 = r_0, r_1, r_2, r_3, r_4$$

which could have up to 1 error.

(a) First, let's locate the error, using an error-locating polynomial $E(x)$. Let $Q(x) = P(x)E(x)$. Recall that

$$Q(i) = P(i)E(i) = r_i E(i), \quad \text{for} \quad 0 \leq i < n + 2k.$$

What is the degree of $E(x)$? What is the degree of $Q(x)$? Using the relation above, write out the form of $E(x)$ and $Q(x)$ in terms of the unknown coefficients, and then a system of equations to find both these polynomials.

(b) Solve for $Q(x)$ and $E(x)$. Where is the error located?

(c) Finally, what is $P(x)$? Use $P(x)$ to determine the original message that Hector wanted to send.
Hint: The message refers to a US federal agency.
